The Web (part 2)

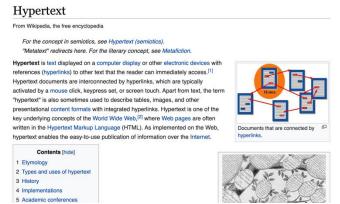

Lecture 7

http://www.cs.rutgers.edu/~sn624/352-F24

Srinivas Narayana

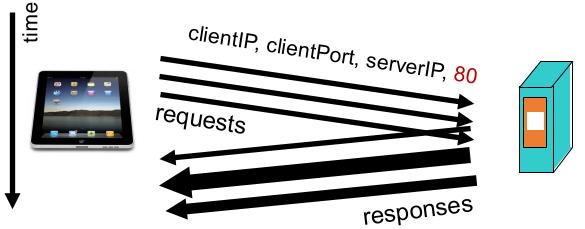

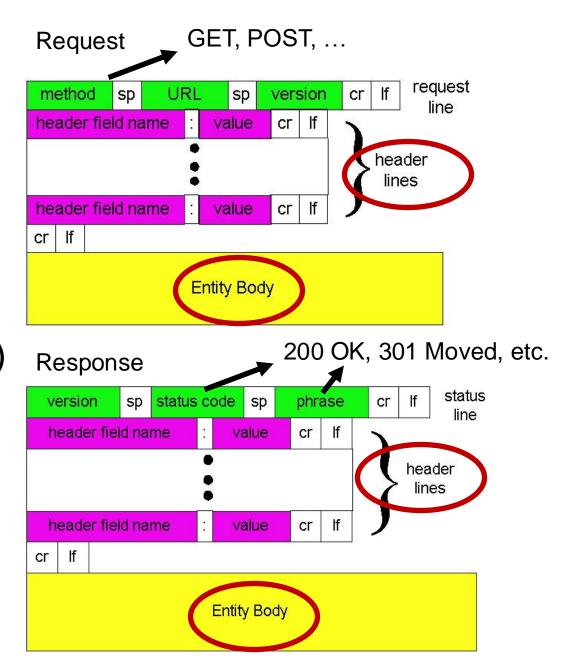

Review of concepts

HyperText Transfer Protocol (HTTP)

Client-Server Protocol

HTTP Persistence

Two types of HTTP connectivity

Non-persistent HTTP

 At most one object is sent over a TCP connection.

HTTP/1.0 uses non-persistent connections

Persistent HTTP

 Multiple objects can be sent over single TCP connection between client and server.

 HTTP/1.1 uses persistent connections in default mode

TCP is a reliable communication protocol provided by the transport layer. It requires setting up some resources (e.g., memory regions) for the connection to be set up at the endpoints before data communication.

Non-persistent HTTP (HTTP/1.0)

1a. HTTP client initiates TCP connection to HTTP server

1b. HTTP server at host "accepts" connection, notifying client

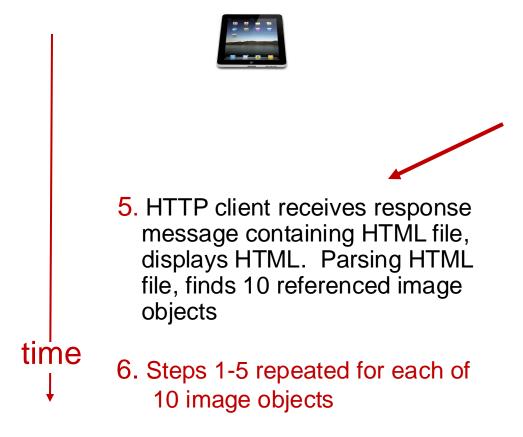

Suppose a user visits a page with text and 10 embedded images.

2. HTTP client sends HTTP request message

 HTTP server receives request message, replies with response message containing requested object

Non-persistent HTTP (HTTP/1.0)

4. HTTP server closes TCP connection.

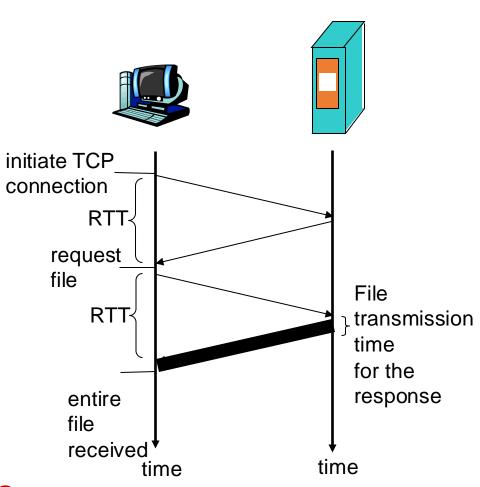

Single connection per object

Useful at a time when web pages contained 1 object: the base HTML file.

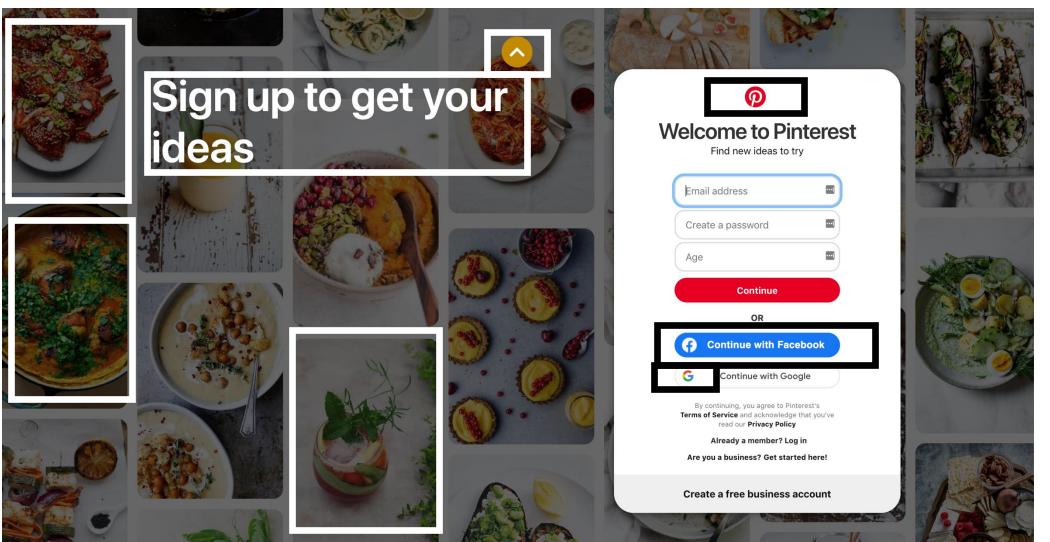

How long does it take to download an entire web page with non-persistent HTTP?
i.e.: before your browser can load the (entire) web page?

Non-persistent HTTP user response time

- Total delay = propagation + queueing + transmission
- Response time for the user
 - = sum of forward and backward total delays
- Round-Trip Time (RTT): total forward + backward delay for a "small" packet
 - Zero transmission delay
- Assumptions:
 - TCP initiation packet, response, HTTP requests are all "small" packets
 - No processing delays at the server
 - RTT is stable over time
- (2RTT + file transmission time) * #objects

Per-object overheads quickly add up

Modern web pages have 100s of objects in them.

Objects (e.g. images) may not be small.

Persistent HTTP (HTTP/1.1)

1a. HTTP client initiates TCP connection to HTTP server

1b. HTTP server at host "accepts"

connection, notifying client

Suppose user visits a page with text and 10 images.

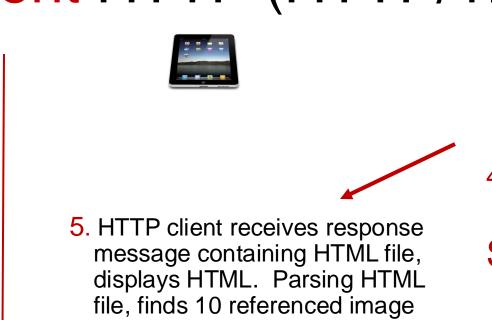

2. HTTP client sends HTTP request message

3. HTTP ser message message message object object

 HTTP server receives request message, replies with response message containing requested object

time

Persistent HTTP (HTTP/1.1)

4. HTTP server sends a response.

objects

Server keeps the TCP connection alive.

time

The 10 objects can be requested over the same TCP connection.

i.e., save an RTT per object (otherwise spent opening a new TCP connection in HTTP/1.0)

Persistent HTTP user response time

- Assume requests made one at a time (separate RTT per req)
- RTT + (RTT + file transmission time) * #objects
- Pipelining: send more than one HTTP request at a time
 - Extreme case: all requests in one (small) packet
 - RTT + (file transmission time) * #objects
 - In practice, dependencies between objects
- Compare with non-persistent:
 - (2RTT + file transmission time) * #objects
- Persistence (& pipelining) can save significant time, especially on high-RTT connections
- Other advantages of persistence: CPU savings, reduced network congestion, less memory (fewer connections)

Persistence vs. # of connections

 Persistence is distinct from the number of concurrent connections made by a client

- Your browser has the choice to open multiple connections to a server
 - HTTP spec suggests to limit this to a small number (2)
- Further, a single connection can have multiple HTTP requests in flight (pipelining) with persistent HTTP

 Clients that use persistent connections SHOULD limit the

Clients that use persistent connections SHOULD limit the number of simultaneous connections that they maintain to a given server. A single-user client SHOULD NOT maintain more than 2 connections with any server or proxy. A proxy SHOULD use up to 2*N connections to another server or proxy, where N is the number of simultaneously active users. These guidelines are intended to improve HTTP response times and avoid congestion.

Remembering Users On the Web

HTTP: Remembering users

So far, HTTP mechanisms considered stateless

- Each request processed independently at the server
- The server maintains no memory about past client requests

However, state, i.e., memory, about the user at the server, is very useful!

- User authentication (e.g., gmail)
- Shopping carts (e.g., Amazon)
- Video recommendations (e.g., Netflix)
- Any user session state in general

Familiar with these?

Your Privacy

We use cookies to make sure that our website works properly, as well as some 'optional' cookies to personalise content and advertising, provide social media features and analyse how people use our site. By accepting some or all optional cookies you give consent to the processing of your personal data, including transfer to third parties, some in countries outside of the European Economic Area that do not offer the same data protection standards as the country where you live. You can decide which optional cookies to accept by clicking on 'Manage Settings', where you can also find more information about how your personal data is processed. Further information can be found in our <u>privacy policy</u>.

Accept all cookies

Cookies: Keeping user memory

How cookies work

Collaboration between client and server to track user state.

Four components:

- 1. cookie header line of HTTP response message
- 2. cookie header line in HTTP request message
- 3. cookie file kept on user endpoint, managed by user's browser
- 4. back-end database maps cookie to user data at Web endpoint

Cookies come with an expiration date (yet another HTTP header)

Cookies have many uses

- The good: Awesome user-facing functionality
 - Shopping carts, auth, ... very challenging or impossible without it
- The bad: Unnecessary recording of your activities on the site
 - First-party cookies: performance statistics, user engagement, ...
- The ugly: Tracking your activities across the Internet
 - Third-party cookies (played by ad and tracking networks) to track your activities across the Internet
 - personally identifiable information (PII)
 - Ad networks target users with ads; may sell this info
 - Scammers can target you too

PSA: Cookies and Privacy

- Disable and delete unnecessary cookies by default
- Suggested privacy-conscious browsers, websites, tools:
- DuckDuckGo (search)
- Brave (browser)
- AdBlock Plus (extension)
- ToR (distract targeting)
- ... assuming it doesn't break the functions of the site

Web Caching

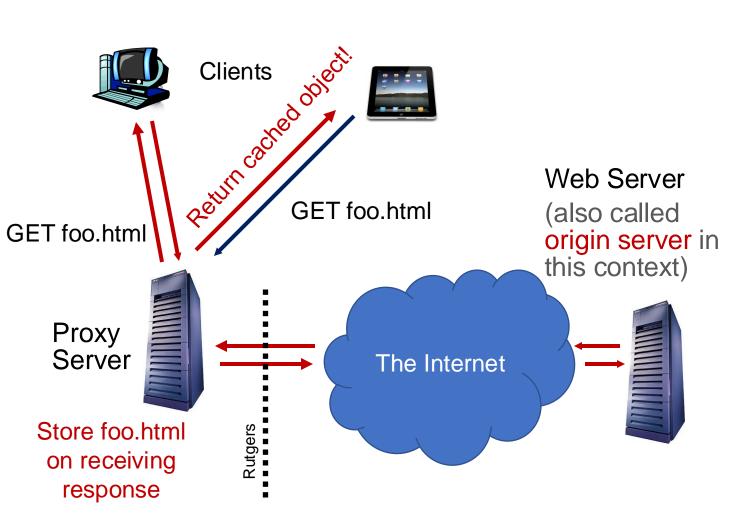

Web caches

Web caches: Machines that remember web responses for a network

Why cache web responses?

- Reduce response time for client requests
- Reduce traffic on an organization's access link

Web caching using a proxy server

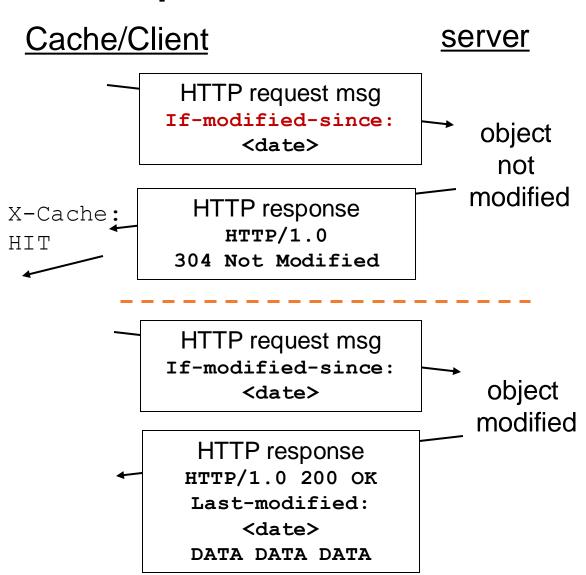

- You can configure a HTTP proxy on your laptop's network settings.
- If you do, your browser sends all HTTP requests to the proxy (cache).
- Hit: cache returns object
- Miss: obtain object from originating web server (origin server) and return to client
 - Also cache the object locally

Caching in the HTTP protocol

Conditional GET
 guarantees cache content
 is up-to-date while still
 saves traffic and response
 time whenever possible

 Date in the cache's request is the last time the server provided in its response header Last-Modified

Content Distribution Networks (CDNs)

A global network of web caches

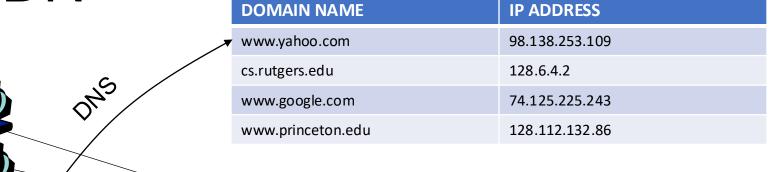

- Provisioned by ISPs and network operators
- Or content providers, like Netflix, Google, etc.

Uses (overlaps with uses of web caching in general)

- Reduce traffic on a network's Internet connection, e.g., Rutgers
- Improve response time for users: CDN nodes are closer to users than origin servers (servers holding original content)
- Reduce bandwidth requirements on the content provider
- Reduce cost to maintain origin servers

Without CDN

Clients
distributed
all over the
world

Cluster of Rutgers CS origin servers (located in NJ, USA)

- Problems:
- Huge bandwidth requirements for Rutgers
- Large propagation delays to reach users

Where the CDN comes in

- Distribute content of the origin server over geographically distributed CDN servers
- But how will users get to these CDN servers?
- Use DNS!
 - DNS provides an additional layer of indirection
 - Instead of returning an IP address, return another DNS server (NS record)
 - Much like a response to any other iterative query
 - The second DNS server (run by the CDN) returns the IP address of the client
- The CDN runs its own DNS servers (CDN name servers)
 - Custom logic to send users to the "closest" CDN web server

DOMAIN NAME IP ADDRESS www.yahoo.com 98.138.253.109 With CDN cs.rutgers.edu 124.8.9.8 (NS record pointing to CDN name server) Mon www.google.com 74.125.225.243

CDN Name Server (124.8.9.8)

IP ADDRESS DOMAIN NAME Cs.Rutgers.edu 12.1.2.3 Cs.Rutgers.edu 12.1.2.4 Cs.Rutgers.edu 12.1.2.5 Cs.Rutgers.edu 12.1.2.6 Using CDN

Custom logic to map ONE domain name to one of many IP addresses!

Popular CDNs: CloudFlare Akamai

NS record delegates the

choice of IP address to

the CDN name server.

Level3

12.1.2.3 12.1.2.4 CDN servers 12.1.2.6 12.1.2.5 Client

128.6.4.2

Origin server

Most requests go to CDN servers (caches). CDN servers may request object from origin Few client requests go directly to origin server

Seeing a CDN in action

• dig +trace freshtohome.com

• dig web.mit.edu (or) dig +trace web.mit.edu

Summary of HTTP

- Request/response protocol
- ASCII-based human-readable message structures
- Enhanced stateful functionality using cookies
- Improve performance using caching and CDN
- Persistence and pipelining to improve performance
- Simple, highly-customizable protocol
 - Just add headers
- The protocol that is the basis of the web we enjoy today
